1620 DIAGNOSTICS

Test CU01

A. SCOPE:

This test is essentially a fault detection test designed to check for proper functioning of all standard operation codes, the optional feature DIVIDE operation codes, and the circuitry associated with these codes. Failure of an operation to function properly will cause the associated routine number to be typed out (provided Switch #1 is OFF). However, since the operation code and E time triggers are known for each routine, a failure of one routine will indicate the circuits or components that may be the source of the trouble. Failure of several routines may establish a pattern that will further isolate the failing component(s).

B. SET UP:

Seven switches must be set for the desired operation. These are the three check switches, Data Check Switch, Overflow Check Switch, I/O Check Switch. If set in the PROGRAM position, a check error will not cause a machine stop; only the light will be turned on and the indicator can be interrogated and turned off by the running program. If set in the STOP position, the program will halt at the end of the memory cycle which causes the indicator to turn on. The suggested settings for these switches when running CU01 are Data Check - Stop; I/O - Stop; Overflow - Program. On suffix A machines, there is no I/O Check Switch; there is a MAR Check Switch which should be set to stop.

The four console Sense switches have the following functions in this test and should be set as desired: (SUGGESTED SETTING, ALL SWITCHES OFF)

SWITCH #1	ON	-	Bypass error type out
	OFF	-	Type out routine number on error
SWITCH #2	ON	-	Loop in routine
	OFF	-	Continue to next routine
SWITCH #3	ON	-	Stop on error
	OFF	-	Do not stop on error, continue
SWITCH #4	ON	-	Repeat Test CU01

NORMAL LOAD FROM TAPE READER:

To run the entire test, the paper tape containing the memory load for CU01 must be loaded in the paper tape reader and the reader put in a REEL mode and a READY condition. Also, put the tape punch in the READY condition. The following instruction must be manually inserted in memory locations 00000-00018: 360002400300490082 8. Then RELEASE and START.

B 01116 bypasses initial printout

For Division machines: 360084 00300 49 14004

PN 2128301
EC 404675

NORMAL LOAD FROM CARD I/O

Place card deck for CU01 in read hopper. Load and run in blank cards in punch hopper. Reset 1620. Depress Load key; which will cause the core storage to be loaded for CU01.

Routines with instructions addressing the paper tape reader and paper tape punch are the only routines that are different for card I/O. These differences are minor; i.e., a change to select card reader or card punch instead of paper tape reader or paper tape punch, and a change of P addresses to account for the 80 character positions of the card.

The first eight cards contain loading instructions and the math tables. The first two cards contain 8 instructions. The second through sixth instructions load the math tables at 60 characters per card. The seventh instruction loads core storage positions 00000 to 00060 with the loading instructions and the eighth instruction branches to 00000.

The loading instructions are:

```
11 00030 00060
14 00030 19944
36 00384 00500
47 00000 01200
49 00828 00000
```

The compare instruction in the above routine detects when core storage has been loaded for CU01. An equal comparison indicates that the core storage load is complete, and the program then branches to the routine that types out the setting of the sense switches.

The interlock circuits of the card reader are such that when the read hopper is empty the machine will stop on the next command for a card read. Two cards remain in the read feed. To transport these cards past the read brushes and transmit the data to the 1620 core storage, the 1622 start key must be depressed or two blank cards placed behind the deck when the deck is placed in the hopper. One of these two methods MUST be used to complete the core storage load for CU01 and to commence with the execution of the routines.

The first program executed by CU01 is a check of the console sense switches. The setting of these switches are typed out along with the instruction to set these as desired; then press the START key; HOWEVER, to check DIVIDE if installed, the following operations must be performed BEFORE depressing START:

1. INSERT
2. KEY IN 4914004
3. RELEASE
4. START

These operations will cause the instruction, branch to first division routine, to be written in memory positions 13992 - 13998, and then branch to 00552.

Division is an optional feature; although the routines to check out division are included in the program. If division is not installed, the load dividend and the divide OP codes are not valid and would cause the machine to "hang-up" when entered in the OP register and an execution attempted. Thus, a branch operation to skip the division routines is included in the program. This instruction must be altered to check division.

ENTER SINGLE ROUTINE FROM KEYBOARD

A single routine can be entered from the keyboard in the following manner:

1. Manually insert the instructions 36xxxxx0010049yyyyy from the keyboard. (xxxxx is the first memory location of the routine. In most cases it is the first position of the constant or working area. yyyyy is the first instruction of the sub-routine.)
2. Then release and start. The machine will "hang-up" waiting for information from the keyboard.
3. Key in the constants and instructions of the routine. Then release and start.
4. With Switch #2 on, the machine will loop in this routine. NOTE: If the instruction involves arithmetics, the arithmetic tables must be loaded in memory locations 100-399.

PRODUCE NEW PAPER TAPE:

To regenerate or produce another tape for input, read in the MASTER tape. When the machine halts after typing out the status of the program sense switches, Reset, Insert, key in the instructions 35000240020048, Release, Start.

C. TEST METHOD:

This test is made up of a number of sub-routines. Each sub-routine checks an operation code for specific condition and can be run as an individual test. Each sub-routine has associated with it constants and a working area, the test routine, and an error routine; and these take a block of memory. No other routine will use this block of memory. The only exception is arithmetics, where the add and multiply tables and the product area are involved.

The test was designed to first check out the more simple decision elements to determine their proper operation. As a decision element was proved to be working correctly, it was used to check the next more complicated routine.

The test starts with Checking out Branch No Record Mark, then proceeds to checkout Branch No Flag, Branch on Digit, Branch Indicate, Branch No Indicate, Transmit Digit, Transmit Digit (Immediate), Transmit Field, Transmit Field (Immediate), Transmit Record, Branch and Transmit, Branch Back, Branch and Transmit (Immediate), Set Flag, Clear Flag, Add, Add (Immediate), Subtract, Subtract (Immediate), Compare, Compare (Immediate), Multiply, Multiply (Immediate), Control, Write Numerically, Write Alphanumerically, Dump Numerically. Load Dividend, Load Dividend (Immediate), Divide, Divide (Immediate) are checked just prior to the control check if the instructions are followed.

Routines in CU01, other than those that check Input-Output operations, are performed 1000 times. This is done to give a good exercise to the logic and to have the program run for an interval of time that can be visually noted. The 1000 repeat takes in the order of 150 seconds (without division).

Upon completion of the 1000th loop, the program enters the routines (077-079) for checking the Input-Output functions.

Routine 077 checks carriage return, tab, space, write numeric, and write alphanumeric operations.

Routine 078 checks dump numeric, and routine 079 checks write alpha on cards or paper tape. After these routines are completed, the machine enters the "completed test" routine. The machine will halt if Switch #4 is OFF.

The typeout of routines 077 - 079 should appear as follows:

```
    12345 67890
    12345 67890 12345
    12345 67890
NUM INFO ABOVE OFFSET TO RIGHT TWO SPACES BETWEEN
5 AND 6 THREE LINES OF DATA.
1997601234567891̄2̄199989
```

The characters that appear on the left margin and the length of the lines will depend upon the setup of the typewriter. The first tab stop should be at least [illegible] characters from the left-hand margin.

To check the paper tape output, load paper tape in reader after system has come to a HALT after performing CU01. Select the STRIP mode. START. The output tape will then be read into memory and typed out. The dump numeric information should be identical to that which was dumped to the typewriter except that the record work is omitted. Three identical groups of write alpha data will be typed out.

```
    1997601234567891̄2̄199989
.)+$*-/,(=@ ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456789
.)+$*-/,(=@ ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456789
.)+$*-/,(=@ ABCDEFGHIJKLMNOPQRSTUVWXYZ0123456789
```

Routine 097 checks for proper operation of the arithmetic indicators and BI and BNI on these indicators.

Typical error typeouts are H followed by the routine number. If the first digit following the H is a 5, this indicates that it is a sub-routine associated with the routine designated by the last two digits; i.e., (H529 or H016). H529 is a subroutine of routine 29.

The complete normal typeout information will be as follows: (Note: The numbers after "THEN START" are present only if DIVIDE is installed and checked.)

```
SW 1 OFF SW 2 OFF SW 3 OFF SW 4 OFF SET SWS FOR CU01.
  THEN START. 4914004
